

## Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact [support@jstor.org](mailto:support@jstor.org).

## SHAFT-SINKING BY FREEZING.

THE method of shaft-sinking recently invented by Mr. F. H. Poetsch of Aschersleben, by means of the artificial production of low temperatures, is an illustration of the new and unexpected directions in which chemical and physical processes become of use. In sinking shafts for mining and other engineering purposes, and in the construction of deep foundations, the presence of quicksand has always been dreaded; for it can be penetrated, if at all, only with great difficulty and expense. While the use of compressed air has enabled us to sink shafts and place foundations in water-bearing strata, we are limited to depths not much exceeding one hundred feet by the practical inability of the human system to endure greater air-pressures. Mr. Poetsch has successfully applied to such cases a method of shaft-sinking by freezing, which bids fair to remove all the trouble. He proposes to do away with the pumps and air-compressors, to transform the surrounding liquid soil into a solid wall of ice, and in this way to reduce the problem of shaft-sinking to that of work in hard, dry ground.

A system of tubes is sunk around and within the site of the proposed shaft, and a saline solution such as chloride of calcium, of very low temperature, having for its freezing-point  $-40^{\circ}$  F., and passed through a Carré ice-machine, is caused to circulate through the system by means of inner tubes until the semi-fluid soil is solidified by congelation. The temperature of the ground has been reduced, in actual work, from  $52^{\circ}$  F. to  $0^{\circ}$  F. in twenty days, freezing within a circle of about five feet diameter around each pipe, and producing in the quicksand the solidity of sandstone, with all its properties of stability, and a conchoidal fracture.

The method of putting in place the freezing-pipes varies with the locality. When the quicksand has a slight thickness only, and the shaft is already sunk to the water-level, the pipes are simply forced into the sand with a sand-pump working inside. This was the system actually employed at the Archibald mine, near Schneidlingen, Prussia, where twenty-three pipes nearly eight inches in diameter were sunk through a water-bearing stratum eighteen feet thick, and at the Max mine, near Michalkowitz, Upper Silesia. In other cases a boring-machine is used which puts down four pipes at a time, and is worked by the water-jet system. If the fluid soil lies at no great depth, the holes for the pipes are bored from the surface, and the pipes are so arranged that the shaft can be sunk inside of them; but, when the water-stratum is at a great depth below the surface, a shaft of some three feet greater diameter than the finished shaft is first sunk through the firm ground, so as to permit of the sinking of the pipes through the fluid stratum, and the construction of the final shaft within them.

At the Centrum mine, near Berlin, one hundred and seven feet of quicksand had to be penetrated. Engineers had been baffled for years in their attempts to overcome the difficulties. In thirty-three days,

with sixteen pipes, Mr. Poetsch had secured a wall of ice six feet thick around the shaft area, and the shaft is now being excavated and curbed without special difficulty.

A series of bridge-piers is to be sunk by this method near Bucharest, Austria. This last contract has especial interest; as it will afford a test of the seemingly just claim of the inventor, that his plan opens up great possibilities in founding bridge-piers. As opposed to the compressed-air process, the main advantages are in the practical absence of limitation in depth, and the relief of the laborers from the effects of severe air-pressures. The entire plant can be used repeatedly, as the pipes can be withdrawn as soon as the ground thaws out. The cost of an undertaking can also be estimated in advance with reasonable certainty.

A more detailed description of this process is given in the *Engineering news*, June 7, 1884, based on an article from the *Zeitschrift für berg., hutten., und salinenwesen in Preussischen staate*, and in the *Engineering news*, July 5, 1884, with illustrations of the plant used at the Centrum mine.

CHAS. E. GREENE.

## AMERICAN ORIENTAL SOCIETY.

THE American oriental society held its autumn meeting at the Johns Hopkins university in Baltimore on Wednesday and Thursday, Oct. 29 and 30. A grammar of the Siamese language was reported as nearly finished by one of the members, Rev. S. C. George. A vocabulary of the Mortlock dialect had been offered to the society for publication by a missionary in the Caroline Islands, and a translation of the Prem Sagar from the original Hindi by the Rev. J. M. Jamieson. The Peking missionary association sent resolutions respecting the eminent Sinologue, Dr. S. W. Williams, the lately deceased president of the Oriental society.

Fourteen papers were presented to the society. The extreme east was represented by a paper on the Korean numerals and alphabet. Mr. Rockhill, an *attaché* of the U. S. embassy to China, presented to the library a Tibetan book of poems by Milaraspa, a Buddhist missionary of the eleventh century; and his paper gave an account of the work, with specimen translations. The president of the society, Professor Whitney of Yale, discussed a group of aorist-forms in Sanscrit. The forms in question are of especial interest, inasmuch as they furnish a good test-case for the general trustworthiness of the Hindu science of grammar, as compared with the most modern treatment of the subject. Professor Bloomfield of Johns Hopkins discussed the position of the Vaitana sutra in the literature of the Atharva-veda, an important text of which, the Kauçika sutra, he is now editing. Several Syriac and Hebrew papers of value were presented; but we must pass them by for want of sufficient space.

In Assyriology, finally, there was an account by Professor Lyon of Harvard, of the last instalment of
